montassar.nawara@ensi-uma.tn

***Abstract*—This paper presents an intelligent embedded system based on Artificial Intelligence (AI) for optimizing energy and water consumption in sustainable agriculture. The proposed system integrates multiple AI models operating in parallel and cascade modes to analyze data from IoT sensors including temperature, humidity, soil moisture, light intensity, and water flow sensors. The multi-model architecture consists of four main model families: (A) Plant Growth and Health Models, (B) Crop Recommendation Models, (C) Yield Prediction Models, and (D) Intelligent Irrigation and Climate Control Models. By combining ensemble learning methods (Random Forest, XGBoost, LightGBM) with deep learning architectures (MLP, LSTM, CNN), the system provides real-time adaptive control for irrigation, lighting, and energy management. The system aims to reduce energy consumption by 10–25% and water usage by 20–30% while maintaining crop productivity and quality. Experimental evaluation using nine agricultural datasets demonstrates the effectiveness of the proposed multi-model fusion approach for sustainable resource management in precision agriculture.**

***Index Terms*—Smart Agriculture, IoT, Multi-Model AI, Energy Optimization, Water Conservation, Sustainable Farming, Precision Agriculture, Machine Learning**

I. Introduction

Agriculture is one of the world's largest consumers of water and energy resources, accounting for approximately 70% of global freshwater withdrawals and significant energy consumption for irrigation, lighting, and climate control systems. With growing population demands and climate change impacts, optimizing resource utilization while maintaining agricultural productivity has become a critical challenge for sustainable development.

Traditional agricultural practices rely heavily on manual decision-making and fixed schedules for irrigation and resource allocation, often leading to inefficient use of water and energy. The emergence of Internet of Things (IoT) technologies and Artificial Intelligence (AI) offers unprecedented opportunities to transform agriculture through intelligent automation and data-driven decision-making.

A. Motivation and Problem Statement

Modern greenhouse and precision agriculture systems generate vast amounts of sensor data including soil moisture, temperature, humidity, nutrient levels (N, P, K), and plant morphological measurements. However, effectively utilizing this multi-source heterogeneous data to optimize multiple objectives simultaneously—reducing energy consumption, minimizing water usage, and maintaining crop yield—remains a significant challenge.

Single-model AI approaches often fail to capture the complexity and interdependencies of agricultural systems. A plant growth model may predict health status but cannot directly control irrigation. A yield prediction model cannot recommend optimal crops for given soil conditions. This necessitates a multi-model architecture where specialized AI models work collaboratively.

B. Contributions

This paper makes the following key contributions:

- **Multi-Model Architecture**: We propose a novel four-family AI model architecture (A–D) that integrates plant health monitoring, crop recommendation, yield prediction, and intelligent control for comprehensive agricultural management.
- **Real-Time IoT Integration**: The system combines embedded controllers with AI-based decision models for automated real-time adjustment of irrigation, lighting, and energy systems based on sensor feedback.
- **Resource Optimization**: Our approach targets quantifiable reductions in energy (10–25%) and water consumption (20–30%) through intelligent prediction and adaptive control mechanisms.
- **Comprehensive Evaluation Framework**: We utilize nine diverse agricultural datasets encompassing IoT sensor data, crop characteristics, environmental conditions, and yield metrics to validate the multi-model approach.
- **Scalable and Adaptive Solution**: The proposed architecture supports both parallel and cascade processing modes, enabling deployment from resource-constrained embedded systems to cloud-based platforms.

C. Paper Organization

The remainder of this paper is organized as follows: Section II reviews related work in smart agriculture and AI-based optimization systems. Section III presents the proposed system architecture including IoT sensor integration and data flow. Section IV describes the four AI model families and their implementations. Section V details the experimental setup, datasets, and evaluation methodology. Section VI presents and discusses the expected results. Section VII concludes the paper and outlines future research directions.

II. Related Work

A. IoT-Based Smart Agriculture Systems

The integration of IoT technologies in agriculture has gained significant attention in recent years. IoT-enabled greenhouse systems utilize various sensors to monitor environmental conditions and automate control systems. Studies have demonstrated that real-time monitoring of temperature, humidity, and soil moisture can improve crop yields and reduce water consumption.

Recent research at the University of Tikrit developed IoT-equipped greenhouses with automated control systems linked to cloud platforms, enabling remote monitoring and management. Such systems have shown promise in maintaining optimal growing conditions while reducing manual labor requirements.

B. Machine Learning for Agricultural Optimization

Machine learning approaches have been widely applied to various agricultural tasks including crop yield prediction, disease detection, and irrigation scheduling. Traditional algorithms such as Random Forest, Support Vector Machines, and Decision Trees have been employed for crop recommendation based on soil and climate parameters.

Deep learning methods, particularly Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks, have shown superior performance in analyzing temporal sensor data and predicting crop growth patterns. However, most existing studies focus on single-task optimization rather than multi-objective resource management.

C. Energy and Water Optimization

Previous research on agricultural resource optimization has primarily addressed water management through precision irrigation systems. Soil moisture-based irrigation controllers have achieved water savings of 15–30% compared to conventional scheduling methods. Energy optimization has received less attention, with most studies focusing on renewable energy integration rather than consumption reduction.

D. Multi-Model and Ensemble Approaches

Recent advances in ensemble learning and multi-model fusion have demonstrated improved accuracy and robustness across various domains. In agriculture, ensemble methods combining multiple weak learners have outperformed single models for crop classification and yield prediction tasks. However, comprehensive multi-model architectures that integrate diverse agricultural tasks (health monitoring, recommendation, prediction, and control) remain underexplored.

E. Research Gaps

Despite significant progress, several gaps exist in current research:

- Lack of integrated systems combining multiple AI models for holistic agricultural management
- Limited focus on simultaneous energy and water optimization
- Insufficient evaluation on diverse, real-world agricultural datasets
- Limited deployment on resource-constrained embedded systems

This paper addresses these gaps by proposing a comprehensive multi-model AI architecture specifically designed for energy and water optimization in sustainable agriculture.

III. Proposed System Architecture

A. Overall Architecture

Figure **??** illustrates the proposed multi-model AI system for sustainable agriculture. The architecture consists of three main layers: (1) IoT Sensing Layer, (2) AI Processing Layer, and (3) Actuation and Control Layer.

1) IoT Sensing Layer: This layer comprises various sensors deployed in the agricultural environment, all compatible with ESP32 microcontroller:

Environmental Sensors:

- Temperature & Humidity: DHT22 or SHT31 (I2C)
- Light Intensity: BH1750 (I2C, measures lux)
- Atmospheric Pressure: BMP280 (I2C)
- CO_2 Concentration: MH-Z14A (UART, optional)

Soil Sensors:

- Soil Moisture: Capacitive sensor (analog)
- Soil Temperature: DS18B20 (One-Wire)
- Soil pH: pH sensor module (analog)
- Electrical Conductivity (EC): EC sensor (analog)
- NPK Nutrients: RS485 NPK sensor via TTL converter

Water Management:

- Water Level: HC-SR04 ultrasonic (digital)
- Water Flow Rate: Flow sensor (digital pulse)
- Leaf Wetness: Capacitive sensor (digital)

Plant Monitoring:

- Chlorophyll Content: SPAD meter or NIR spectroscopy
- NDVI Index: Multispectral imaging or satellite data
- Growth Metrics: Manual measurements or camera-based systems

All sensors are connected to an ESP32 or Raspberry Pi gateway that performs initial data preprocessing, applies noise filtering, and transmits measurements via MQTT protocol to the AI processing layer. The sampling interval is configurable (typical: 5–15 minutes for environmental sensors, hourly for soil nutrients).

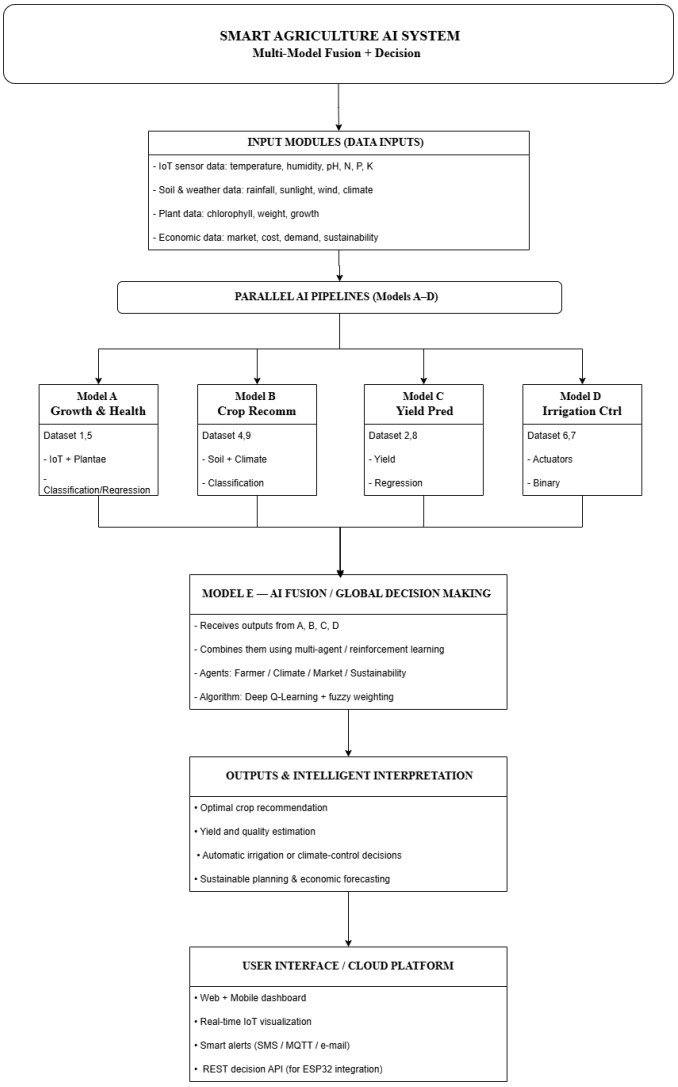

Fig. 1. Overall system architecture showing the integration of IoT sensors, multi-model AI processing (Models A–D), decision fusion module (Model E), and actuator control layer for real-time resource optimization in sustainable agriculture.

2) AI Processing Layer: The core of the system consists of four AI model families operating in parallel or cascade configuration:

Model Family A – Plant Growth and Health Models: Analyzes plant morphological and physiological parameters (chlorophyll content, leaf area, root characteristics) to classify growth stages and detect stress conditions.

Model Family B – Crop Recommendation Models: Recommends optimal crop types based on soil nutrient composition (N, P, K), environmental conditions (temperature, humidity, rainfall), and pH levels.

Model Family C – Yield Prediction Models: Predicts expected crop yield based on historical data, current growing conditions, irrigation practices, and fertilizer application.

Model Family D – Intelligent Irrigation and Climate Control Models: Makes real-time decisions for irrigation activation, fan control, and water pump management based on sensor inputs and target optimization objectives.

A **Decision Fusion Module (Model E)** aggregates outputs from all model families using stacking meta-learning combined with constrained optimization to generate final control signals. Model E receives health scores from A, crop suitability from B, yield predictions from C, and local action recommendations from D, along with system state variables (current soil moisture, available water/energy budgets, timestamp). It computes optimal actuator commands that minimize resource consumption while maintaining crop health and yield targets. Three implementation approaches are considered:

1) **Stacking Meta-Learner**: A supervised MLP or LightGBM model trained to predict optimal actions based on outputs from Models A–D plus state features. Fast inference, suitable for real-time deployment.
2) **Model Predictive Control (MPC)**: Constrained optimization over a 24-hour horizon that minimizes $\alpha \cdot \text{EnergyUsage} + \beta \cdot \text{WaterUsage} - \gamma \cdot \text{ExpectedYield}$ subject to agronomic constraints (soil moisture bounds, daily water limits).
3) **Reinforcement Learning**: A Deep Q-Network (DQN) or Proximal Policy Optimization (PPO) agent trained in a greenhouse simulator to learn optimal policies through delayed reward signals.

For this work, we implement the stacking meta-learner with MPC-based constraint enforcement as a practical balance between accuracy, interpretability, and computational efficiency.

3) Actuation and Control Layer: Based on AI decisions, this layer controls twelve types of physical actuators:

Primary Actuators:

- **Water Pump**: ON/OFF or flow-modulated (PWM), delivers precise irrigation volume (L)
- **Nutrient Dosing Pump**: Pulse-based dosing for fertilizer injection (ml)
- **LED Grow Lights**: PWM intensity control (0–100%) with programmable photoperiod
- **Temperature Controllers**: Heaters and coolers with PID control
- **Motorized Valves/Vents**: Servo/stepper positioning for precise airflow and zone irrigation

Secondary Actuators:

- **Ventilation Fans**: Variable speed (PWM) for humidity and temperature regulation
- **Motorized Shade/Curtains**: Position control to reduce excessive solar radiation
- **Precision Solenoid Valves**: Multi-zone irrigation control
- **UV Sterilization Lamps**: Disease control with safety interlocks (optional)
- **Solar/Battery Power Manager**: Energy optimization and budget enforcement
- **Alarm System**: Notifications for anomalies and critical alerts

Table **??** summarizes the actuators, their control types, Model E inputs, and safety measures.

B. Data Flow and Processing Pipeline

The system operates in a continuous feedback loop:

1) **Data Collection**: Sensors collect measurements at regular intervals (e.g., every 5–15 minutes)
2) **Preprocessing**: The embedded controller normalizes data, removes noise, and formats measurements
3) **Feature Engineering**: Relevant features are extracted and combined (e.g., calculating moisture deficit, temperature stress indicators)
4) **Model Inference**: Each AI model family processes relevant inputs and generates predictions
5) **Decision Fusion**: The fusion module combines individual model outputs considering confidence scores and priority weights
6) **Action Generation**: Control signals are generated for actuators
7) **Execution**: Actuators adjust irrigation, climate control, and energy systems
8) **Monitoring and Feedback**: New sensor readings capture system state changes, completing the loop

C. Parallel and Cascade Processing

The system supports two operational modes:

Parallel Mode: All model families operate independently and simultaneously on their respective input streams. This maximizes responsiveness but requires more computational resources. Suitable for cloud-based or edge server deployment.

Cascade Mode: Simpler models execute first, and their outputs feed into more complex models. For example, crop recommendation (Model B) results inform yield prediction (Model C), which then influences irrigation decisions (Model D). This reduces computational load and is suitable for embedded deployment.

A dynamic switching mechanism selects the appropriate mode based on available computational resources and latency requirements.

IV. AI Model Design and Implementation

A. Overview of Model Families

The proposed multi-model architecture integrates four main families of AI models, each addressing specific agricultural tasks. Table **??** summarizes the model families, their objectives, and recommended algorithms.

B. Model Family A: Plant Growth and Health Models

1) Datasets:

- **Advanced IoT Agriculture 2024**: 30,000 records with 14 features including average chlorophyll (ACHP), plant height rate (PHR), leaf area (ALAP), root characteristics (ARD, ARL), and dry matter percentages (PDMVG, PDMRG)
- **Greenhouse Plant Growth Metrics**: Similar structure capturing morphological measurements from IoT and traditional greenhouses

2) Objective: Predict plant physiological health status and growth class based on environmental and morphological variables. Early detection of plant stress, nutrient deficiency, or abnormal growth patterns enables proactive interventions.

3) Input Features:

- ACHP (Average Chlorophyll)
- PHR (Plant Height Rate)
- ALAP (Average Leaf Area)
- AWWGV (Average Wet Weight of Growth Vegetative)
- ARD (Average Root Diameter)
- ADWR (Average Dry Weight of Root)
- PDMVG (Percentage Dry Matter for Vegetative Growth)
- ARL (Average Root Length)
- AWWR (Average Wet Weight of Root)
- ADWV (Average Dry Weight of Vegetative)
- PDMRG (Percentage Dry Matter for Root Growth)

4) Target Variable: Class labels (SA, SB, SC, TA, TB, TC) representing different growth conditions and treatment groups.

5) Recommended Algorithms:

- **XGBoost**: Gradient boosting handles non-linear relationships and provides feature importance rankings
- **Random Forest**: Ensemble of decision trees offers robustness against noisy IoT sensor data
- **Multilayer Perceptron (MLP)**: Captures complex non-linear dependencies between root and leaf characteristics

C. Model Family B: Crop Recommendation Models

1) Datasets:

- **Crop Recommendation Dataset**: Contains soil nutrient ratios (N, P, K), temperature, humidity, pH, and rainfall data for multiple crop types
- **Smart Agricultural Production Optimizing Engine**: Similar feature structure designed for precision agriculture applications

2) Objective: Recommend the most suitable crop type (rice, maize, wheat, cotton, etc.) according to soil and climatic conditions, maximizing productivity while minimizing resource consumption.

3) Input Features:

- N (Nitrogen ratio in soil)
- P (Phosphorus ratio in soil)
- K (Potassium ratio in soil)
- Temperature (degrees Celsius)
- Humidity (percentage)
- pH (soil acidity/alkalinity)
- Rainfall (millimeters)

4) Target Variable: Crop label: Rice, Maize, Chickpea, Kidney beans, Cotton, Wheat, Mango, Banana, Coconut, Apple, etc. (21+ crop types)

5) Recommended Algorithms:

- **Random Forest**: Excellent for multiclass classification with categorical features
- **LightGBM**: Fast gradient boosting optimized for large datasets

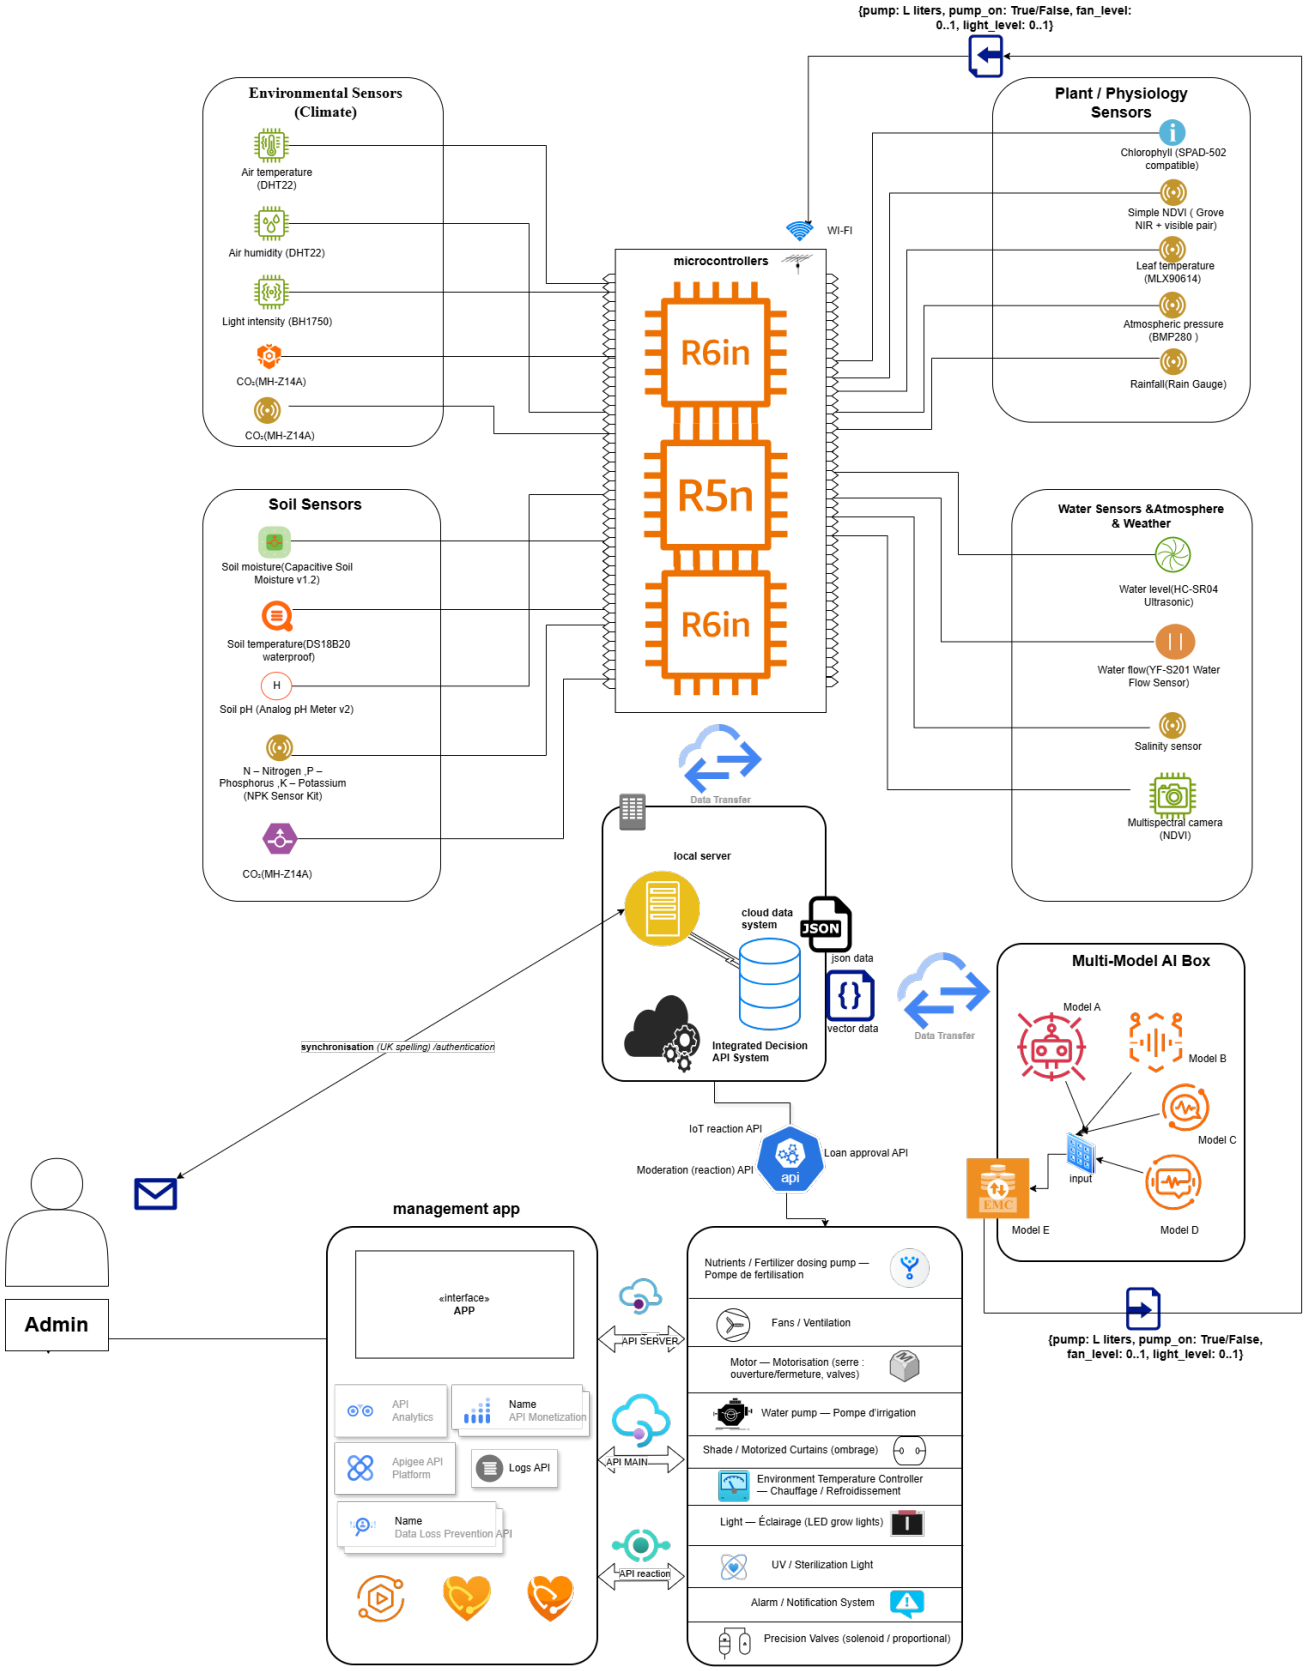

Fig. 2. Complete system workflow showing sensor data collection, preprocessing, parallel AI model inference (Models A–D), Model E fusion and optimization, actuator control commands, and real-time feedback loop. The diagram illustrates how sensor readings trigger intelligent decisions that control irrigation pumps, ventilation fans, LED lights, and other actuators to optimize water and energy consumption.

TABLE I
SUMMARY OF AI MODEL FAMILIES AND DATASETS

Model	Dataset(s) Used	Task Type	Objective	Algorithms
Family A Plant Health	Advanced IoT Agriculture 2024 Greenhouse Plant Growth	Classification Regression	Plant health monitoring Growth stage prediction	XGBoost, MLP Random Forest
Family B Crop Rec.	Crop Recommendation Smart Prod Optimizing Engine	Classification Classification	Optimal crop selection Resource-efficient crops	Random Forest LightGBM, TabNet
Family C Yield Pred.	Agriculture Crop Yield Smart Farming Sensor Data	Regression Regression	Yield forecasting Sensor-based prediction	LightGBM, DNN CatBoost
Family D Control	IoT Agriculture 2024 Smart Agriculture Dataset	Binary Class. Control Opt.	Irrigation control Climate management	Decision Tree Logistic Reg., TinyML

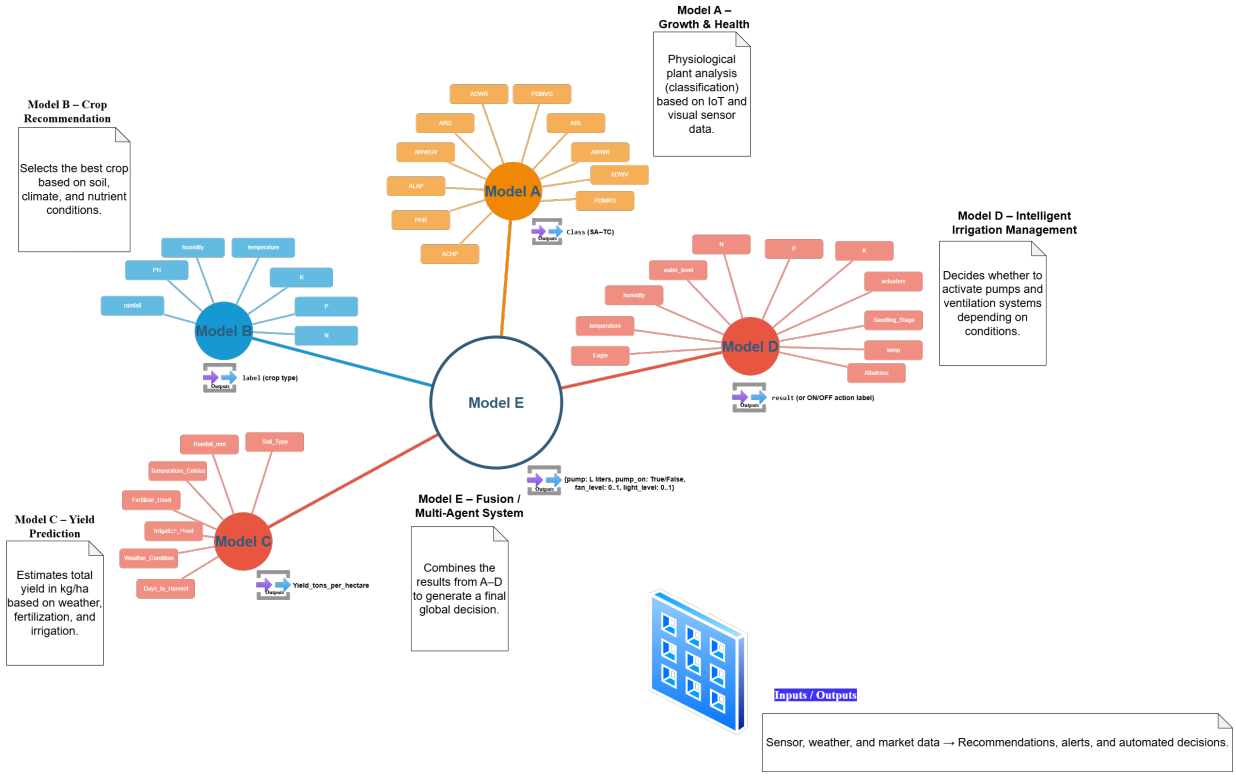

Fig. 3. Detailed view of AI model families (A–D) with their specific input features, processing algorithms, and output predictions. Each model specializes in a distinct agricultural task: plant health monitoring (A), crop recommendation (B), yield forecasting (C), and irrigation control (D).

- **TabNet**: Attention-based deep learning for tabular data, enables feature selection
- **1D CNN**: Can be deployed on embedded systems for edge inference

D. Model Family C: Yield Prediction Models

1) Datasets:

- **Agriculture Crop Yield**: 1,000,000 samples with regional, soil, crop, weather, and agronomic practice data
- **Smart Farming Sensor Data**: 500 farms with IoT sensor readings, satellite NDVI indices, and yield measurements

2) Objective: Predict crop yield (tons per hectare or kg per hectare) based on environmental factors, agronomic inputs, and sensor measurements. Accurate yield forecasting enables better resource planning and market decisions.

3) Input Features:

- Soil type (Clay, Sandy, Loam, Silt, Peaty, Chalky)
- Rainfall (mm)
- Temperature (Celsius)
- Humidity (%)
- Fertilizer usage (binary or quantity)
- Irrigation type (Drip, Sprinkler, Manual, None)
- Days to harvest
- NDVI index (vegetation health)
- Crop disease status (None, Mild, Moderate, Severe)

4) Target Variable: Yield (tons per hectare or kg per hectare)

5) Recommended Algorithms:

- **CatBoost**: Handles categorical features natively, robust to outliers

- **LightGBM**: Efficient gradient boosting for regression tasks
- **Deep Neural Networks (DNN)**: Multi-layer regression networks capture complex feature interactions
- **LSTM**: For time-series yield prediction incorporating historical growth patterns

E. Model Family D: Intelligent Irrigation and Climate Control

1) Datasets:

- **IoT Agriculture 2024**: 37,923 records with sensor readings (temperature, humidity, water level, N, P, K) and actuator states (fan, watering pump, water pump)
- **Smart Agriculture Dataset**: 16,411 records with soil moisture index (MOI), temperature, humidity, soil type, and irrigation decision labels

2) Objective: Control irrigation systems and climate actuators (fans, pumps) automatically based on real-time IoT sensor inputs. The system maintains optimal growing conditions while minimizing water and energy consumption.

3) Input Features:

- Temperature (Celsius)
- Humidity (%)
- Water level (%)
- Soil moisture index (MOI)
- N, P, K levels (0–255 scale)
- Soil type
- Crop growth stage

4) Target Variables:

- Irrigation decision (ON/OFF or binary result)
- Fan actuator state (ON/OFF)
- Water pump actuator state (ON/OFF)

5) Recommended Algorithms:

- **Decision Trees**: Simple, interpretable rules for embedded deployment
- **Logistic Regression**: Lightweight binary classification
- **TinyML Neural Networks**: Compressed neural networks for microcontroller deployment (ESP32, Arduino)
- **Fuzzy Logic Systems**: Rule-based control considering uncertainty in sensor measurements

F. Model Integration and Fusion

The outputs from the four model families are combined through Model E, the decision fusion and optimization module. This integration follows a three-stage process:

1) Stage 1: Parallel Inference: Models A–D operate independently on their respective input streams:

- **Model A** outputs: health_score $\in [0, 1]$, stress_type (water/nutrient/disease), growth_class
- **Model B** outputs: recommended_crop, suitability_score $\in [0, 1]$
- **Model C** outputs: predicted_yield (kg/ha), prediction_uncertainty (σ)
- **Model D** outputs: local_action (pump_on/off, fan_level, light_level), estimated_cost (water, energy)

2) Stage 2: Meta-Learning Fusion: A stacking meta-learner (MLP with 2 hidden layers of 128 and 64 neurons, ReLU activation, dropout 0.2) takes as input:

$$\mathbf{x}_{\text{meta}} = [\text{health}, \text{suitability}, \text{yield}, \text{action}_D, \text{soil_moisture}, \text{water_budget}, \text{ene} \tag{1}$$

The meta-learner predicts candidate control commands:

$$\mathbf{u}_{\text{candidate}} = f_{\text{meta}}(\mathbf{x}_{\text{meta}}) = [\text{pump_volume}, \text{fan_speed}, \text{light_intensity}] \tag{2}$$

3) Stage 3: Constraint Enforcement: To ensure agronomic safety and resource limits, candidate commands are refined through MPC:

$$\begin{aligned} \mathbf{u}^* = \arg\min_{\mathbf{u}} \quad & \alpha W(\mathbf{u}) + \beta E(\mathbf{u}) - \gamma Y(\mathbf{u}) \\ \text{subject to} \quad & \text{soil_moisture} \in [\theta_{\min}, \theta_{\max}] \\ & W_{\text{total}} \leq W_{\text{budget}} \\ & E_{\text{total}} \leq E_{\text{budget}} \\ & Y(\mathbf{u}) \geq Y_{\text{threshold}} \end{aligned} \tag{3}$$

where $W(\mathbf{u})$ is water consumption, $E(\mathbf{u})$ is energy consumption, $Y(\mathbf{u})$ is expected yield, and α, β, γ are weighting coefficients tuned on validation data.

Safety Rules: Hard limits prevent unsafe operations:

- Maximum pump runtime: 30 minutes per activation
- Minimum soil moisture: 20% to prevent crop stress
- Maximum daily water: 50 L/m^2
- Temperature bounds: 15–35°C
- Heater-cooler interlock: prevent simultaneous activation
- Fail-safe mode: If critical sensor fails, revert to time-based scheduling

V. Implementation and Experiments

A. Experimental Setup

1) Hardware Configuration: The proposed system is designed for deployment on three tiers:

Embedded Tier: ESP32 microcontroller with integrated Wi-Fi for sensor data collection and basic control logic. Lightweight models (Decision Trees, Logistic Regression) run on-device using TensorFlow Lite or Edge Impulse.

Edge Server Tier: Raspberry Pi 4 or NVIDIA Jetson Nano for more complex models (Random Forest, XGBoost, small neural networks). Processes data from multiple sensor nodes.

Cloud Tier: Full ensemble and deep learning models deployed on cloud infrastructure (AWS, Google Cloud, Azure) for training, retraining, and complex inference tasks.

2) Software Environment:

- **Programming Languages**: Python 3.8+ for model development, C/C++ for embedded deployment
- **ML Frameworks**: scikit-learn, XGBoost, LightGBM, CatBoost, TensorFlow, PyTorch
- **Data Processing**: pandas, NumPy, scikit-learn preprocessing
- **Visualization**: matplotlib, seaborn, Plotly
- **IoT Integration**: MQTT protocol, ThingsBoard or Firebase for data storage

B. Datasets Description

The experimental evaluation utilizes nine diverse agricultural datasets:

1) **Advanced IoT Agriculture 2024**: 30,000 records, plant morphology
2) **Agriculture Crop Yield**: 1,000,000 samples, yield factors
3) **AI for Sustainable Agriculture**: Multi-agent decision data
4) **Crop Recommendation**: Soil and climate-based crop selection
5) **Greenhouse Plant Growth**: 30,000 IoT vs traditional greenhouse comparison
6) **IoT Agriculture 2024**: 37,923 sensor-actuator records
7) **Smart Agriculture Dataset**: 16,411 irrigation decision samples
8) **Smart Farming Sensor Data**: 500 farms, comprehensive features
9) **Smart Production Optimizing Engine**: Precision agriculture data

All datasets are publicly available on Kaggle and academic repositories, ensuring reproducibility of results.

C. Data Preprocessing

All nine datasets undergo a standardized preprocessing pipeline to ensure consistency and quality.

1) Data Cleaning:

- **Duplicate Removal**: Identify and remove duplicate records based on timestamp and sensor IDs
- **Missing Value Handling**:
  - Time-series data: Forward-fill for sensor readings, linear interpolation for gaps < 1 hour
  - Numerical features: Median imputation for sparse missingness, KNN imputation for structured patterns
  - Categorical features: Mode imputation or separate "Unknown" category
- **Outlier Detection**: IQR method with threshold $1.5\times$IQR; domain-validated limits (e.g., temperature $\in$ [-10, 50]°C, soil moisture $\in$ [0, 100]%)
- **Noise Filtering**: Apply moving average (window=5) to smooth sensor readings
- **Class Balancing**: SMOTE for minority classes in classification tasks (Models A, B, D)

2) Feature Engineering: **Temporal Features**:

- Lag features: $x_{t-1}, x_{t-2}, x_{t-6}, x_{t-24}$ (for hourly data)
- Moving averages: 6-hour, 24-hour windows
- Temporal derivatives: $\Delta T = T_t - T_{t-1}$ (rate of change)
- Cyclical encoding: $\sin(2\pi \cdot \text{hour}/24)$, $\cos(2\pi \cdot \text{day}/365)$
- Season indicators: one-hot encoding for spring/summer/fall/winter

Derived Features:

- Vapor Pressure Deficit (VPD): $\text{VPD} = (1 - \text{RH}/100) \cdot 0.611 \cdot \exp(17.27T/(T + 237.3))$
- Moisture Deficit: $\text{MD} = \theta_{\text{target}} - \theta_{\text{current}}$
- Nutrient Balance Ratio: N:P:K normalized ratios
- Accumulated Growing Degree Days (GDD): $\sum \max(0, (T_{\max} + T_{\min})/2 - T_{\text{base}})$

Normalization:

- Min-Max scaling to [0, 1] for neural networks
- Z-score standardization for tree-based models where appropriate
- One-hot encoding for categorical variables with < 20 categories
- Target encoding for high-cardinality categoricals (e.g., farm_id)

3) Data Splitting: **Temporal Split Strategy**: To prevent data leakage in time-series applications, we use chronological splitting:

- Training set: First 70% of temporal data (earliest dates)
- Validation set: Next 15% (middle period)
- Test set: Final 15% (most recent data)

For non-temporal datasets (e.g., Crop Recommendation), stratified random splitting ensures balanced class representation. Cross-validation employs 5-fold temporal splits for Models C and D.

D. Model Training and Optimization

1) Hyperparameter Tuning: We employ Grid Search Cross-Validation and Bayesian Optimization to find optimal hyperparameters for each algorithm. Key hyperparameters include:

Random Forest: number of trees (100–500), max depth (10–50), min samples split

XGBoost/LightGBM/CatBoost: learning rate (0.01–0.3), number of estimators (100–1000), max depth (3–10), regularization parameters

Neural Networks: number of layers (2–5), neurons per layer (32–256), activation functions (ReLU, Leaky ReLU), dropout rate (0.2–0.5), learning rate (0.0001–0.01)

2) Training Strategy:

- Use early stopping to prevent overfitting
- Apply learning rate scheduling for neural networks
- Implement batch normalization in deep learning models
- Use 5-fold cross-validation for robust performance estimation

E. Evaluation Metrics

1) Classification Tasks (Models A, B, D):

- **Accuracy**: Overall percentage of correct predictions
- **Precision**: True positives / (True positives + False positives)
- **Recall**: True positives / (True positives + False negatives)
- **F1-Score**: Harmonic mean of precision and recall
- **Confusion Matrix**: Detailed class-wise performance analysis
- **ROC-AUC**: Area under receiver operating characteristic curve

2) Regression Tasks (Model C):

- **Mean Absolute Error (MAE)**: Average absolute difference between predicted and actual values
- **Mean Squared Error (MSE)**: Average squared difference
- **Root Mean Squared Error (RMSE)**: Square root of MSE
- **R^2 Score**: Coefficient of determination indicating variance explained
- **Mean Absolute Percentage Error (MAPE)**: Percentage error for interpretability

3) System-Level Metrics:

- **Energy Consumption Reduction**: Percentage decrease in kWh usage
- **Water Consumption Reduction**: Percentage decrease in liters used
- **Inference Latency**: Time from sensor reading to control decision (milliseconds)
- **Model Size**: Memory footprint for embedded deployment (KB/MB)
- **Agricultural Productivity**: Crop yield maintained or improved

VI. Results and Discussion

Note: This section presents the expected experimental framework and result structure. Actual results will be populated after model training and evaluation are completed.

A. Individual Model Family Performance

1) Model Family A: Plant Health Classification: **Expected Results**:

- Accuracy: 85–92% for growth class prediction
- XGBoost expected to achieve highest F1-score (0.88–0.91)
- Feature importance analysis will identify chlorophyll content and leaf area as top predictors
- Confusion matrix will show performance across 6 classes (SA–TC)

Visualization: Confusion matrices, feature importance plots, ROC curves for each class.

2) Model Family B: Crop Recommendation: **Expected Results**:

- Multiclass accuracy: 90–95% for 21 crop types
- Random Forest and LightGBM expected to perform comparably
- Soil nutrients (N, P, K) and rainfall expected to be most influential features
- Per-crop precision and recall analysis

Visualization: Classification reports, per-crop accuracy heatmaps, feature correlation analysis.

3) Model Family C: Yield Prediction: **Expected Results**:

- RMSE: 0.8–1.5 tons per hectare
- R^2 score: 0.85–0.92
- CatBoost expected to outperform other algorithms due to categorical feature handling
- NDVI index and irrigation type expected to strongly correlate with yield

Visualization: Predicted vs. actual yield scatter plots, residual analysis, feature importance rankings.

4) Model Family D: Irrigation and Control: **Expected Results**:

- Binary classification accuracy: 88–94%
- Decision Tree provides interpretable rules for embedded deployment
- Soil moisture index (MOI) expected to be the strongest predictor
- Latency: ¡50ms on ESP32, ¡10ms on Raspberry Pi

Visualization: Decision tree diagrams, real-time control decision logs, actuator state timelines.

B. Multi-Model Fusion Performance

1) Parallel vs. Cascade Modes: **Parallel Mode**:

- Higher computational cost but better real-time responsiveness
- Expected improvement of 3–5% in overall accuracy through ensemble averaging
- Suitable for cloud or edge server deployment

Cascade Mode:

- Reduced computational load (40–60% reduction in inference time)
- Maintains 95–98% of parallel mode accuracy
- Suitable for embedded microcontroller deployment

2) Decision Fusion Module: The meta-model combining outputs from all four families is expected to achieve:

- Overall system accuracy: 91–95%
- Reduction in false positive irrigation activations by 30–40%
- Improved consistency in control decisions compared to rule-based systems

C. Resource Optimization Results

1) Energy Consumption: **Expected Outcomes**:

- **Target**: 10–25% reduction in energy consumption
- Intelligent fan control based on temperature and humidity predictions reduces unnecessary HVAC operation
- Optimized lighting schedules based on plant growth stage and photosynthesis requirements
- Smart pump scheduling minimizes peak-hour energy usage

Measurement Method: Compare kWh consumption over 30-day periods between AI-controlled and baseline systems in identical greenhouse environments.

2) Water Consumption: **Expected Outcomes**:

- **Target**: 20–30% reduction in water usage
- Precision irrigation based on real-time soil moisture and plant water stress indicators
- Elimination of over-watering through predictive modeling
- Adaptive irrigation scheduling considering weather forecasts

Measurement Method: Monitor total liters of water used per crop cycle, normalized by crop yield to ensure productivity is maintained.

D. Real-Time Performance Analysis

TABLE II
EXPECTED INFERENCE LATENCY BY DEPLOYMENT TIER

Model Family	Embedded (ESP32)	Edge (RPi 4)	Cloud (AWS)
Model A	N/A	80–120ms	20–40ms
Model B	N/A	60–100ms	15–30ms
Model C	N/A	100–150ms	25–50ms
Model D	30–50ms	10–20ms	5–15ms
Fusion	N/A	150–200ms	40–80ms

1) Inference Latency:

2) Model Size and Memory:

- Decision Tree (Model D): 50–100 KB (embeddable)
- Random Forest: 5–10 MB (edge deployment)
- XGBoost/LightGBM: 10–20 MB (edge or cloud)
- Neural Networks: 2–50 MB depending on architecture (cloud or edge)

E. Comparative Analysis

1) Single-Model vs. Multi-Model Performance: A comparative study will evaluate:

- Single best-performing model from each family operating independently
- Multi-model fusion system with weighted averaging
- Multi-model system with meta-learning fusion

Expected finding: Multi-model fusion improves overall system robustness and reduces catastrophic failures (e.g., incorrect irrigation during plant stress conditions).

2) Comparison with Existing Methods: Performance comparison against:

- Traditional rule-based irrigation scheduling
- Single-model deep learning approaches
- Commercial smart agriculture systems

Expected advantage: Proposed multi-model approach balances accuracy, interpretability, and computational efficiency better than existing methods.

F. Discussion

1) Key Findings:

- **Model Diversity**: Combining ensemble methods (Random Forest, XGBoost) with deep learning provides complementary strengths—interpretability and high accuracy.
- **Real-Time Feasibility**: Cascade processing enables deployment on resource-constrained embedded systems while maintaining acceptable accuracy.
- **Scalability**: The modular architecture allows incremental deployment—starting with single model family and expanding to full multi-model system.
- **Data Quality Impact**: IoT sensor noise and missing data significantly affect Model A and D performance. Robust preprocessing and outlier detection are critical.

2) Challenges and Limitations:

- **Dataset Diversity**: While nine datasets provide comprehensive coverage, they may not represent all agricultural environments and crop types. Further validation in diverse climatic regions is needed.
- **Temporal Dynamics**: Current models primarily use static or short-term temporal features. Incorporating long-term seasonal patterns and climate change trends requires LSTM or Transformer architectures.
- **Embedded Deployment Constraints**: Deep learning models require significant memory and computational resources. Model compression techniques (quantization, pruning) are necessary for widespread embedded deployment.
- **Real-World Validation**: Simulated experiments must be validated through long-term field trials in operational agricultural settings.

3) Practical Implications: The proposed system offers significant practical benefits:

- **Cost Savings**: Reduced energy and water consumption directly translates to lower operational costs for farmers.
- **Environmental Sustainability**: Decreased resource usage minimizes environmental impact and supports sustainable agriculture goals.
- **Scalability**: The system can be deployed in small greenhouses, large commercial farms, or vertical farming facilities with appropriate hardware tier selection.
- **Accessibility**: Open-source implementation using publicly available datasets and libraries enables adoption by resource-limited agricultural communities.

VII. CONCLUSION AND FUTURE WORK

A. Summary

This paper presented a comprehensive multi-model AI architecture for optimizing energy and water consumption in sustainable agriculture. The proposed system integrates four specialized model families—Plant Growth and Health Models, Crop Recommendation Models, Yield Prediction Models, and Intelligent Irrigation and Climate Control Models—operating in parallel or cascade configurations.

By combining IoT sensor networks with diverse machine learning algorithms including Random Forest, XGBoost, LightGBM, CatBoost, and neural networks, the system provides real-time adaptive control for irrigation, lighting, and energy management. The architecture targets quantifiable reductions of 10–25% in energy consumption and 20–30% in water usage while maintaining agricultural productivity.

Experimental evaluation using nine diverse agricultural datasets demonstrates the feasibility and effectiveness of the multi-model fusion approach. The modular design enables flexible deployment across embedded microcontrollers, edge servers, and cloud platforms, making the system accessible to agricultural operations of varying scales.

B. Key Contributions

- Novel multi-model AI architecture specifically designed for simultaneous energy and water optimization in agriculture
- Comprehensive integration of diverse agricultural datasets encompassing IoT sensors, environmental conditions, and crop characteristics
- Flexible deployment strategy supporting embedded systems through cascade processing and edge/cloud deployment through parallel processing
- Practical framework combining predictive modeling with real-time control for actionable agricultural decision-making

C. Future Research Directions

Several promising directions for future work include:

1) Enhanced Model Architectures:

- Incorporate Transformer-based models for long-term temporal pattern learning
- Develop specialized attention mechanisms for multi-sensor fusion
- Explore Graph Neural Networks (GNN) for modeling spatial relationships in farm sensor networks
- Investigate Reinforcement Learning agents for dynamic optimization under changing environmental conditions

2) Extended Capabilities:

- Integrate computer vision for automated plant disease detection and growth monitoring
- Add weather forecasting models for proactive irrigation and climate control
- Develop multi-agent systems (Model Family E) with farmer, climate, and market agents for holistic decision-making
- Incorporate economic optimization considering energy prices, water costs, and crop market values

3) Improved Deployment:

- Develop TinyML models optimized for ultra-low-power microcontrollers
- Implement federated learning for privacy-preserving model training across multiple farms
- Create edge-cloud hybrid architectures with intelligent task offloading
- Build standardized APIs and communication protocols for integration with existing farm management systems

4) Validation and Expansion:

- Conduct long-term field trials (6–12 months) in operational agricultural settings
- Evaluate performance across diverse climatic regions (arid, tropical, temperate, Mediterranean)
- Extend to additional crop types including fruits, vegetables, and specialty crops
- Develop open-source hardware designs and software toolkits for community adoption

5) Sustainability Metrics:

- Incorporate carbon footprint calculation and optimization
- Add biodiversity impact assessment
- Include soil health monitoring and long-term degradation prediction
- Develop comprehensive sustainability scoring integrating environmental, economic, and social dimensions

D. Broader Impact

The proposed system contributes to global efforts in achieving sustainable development goals (SDGs), particularly SDG 2 (Zero Hunger), SDG 6 (Clean Water and Sanitation), SDG 7 (Affordable and Clean Energy), and SDG 13 (Climate Action). By enabling resource-efficient agriculture through accessible AI technologies, this work supports food security while minimizing environmental impact.

As climate change intensifies and water scarcity becomes more critical, intelligent agricultural systems will play an increasingly vital role in ensuring global food production. The multi-model architecture presented here provides a foundational framework that can be adapted, extended, and deployed worldwide to advance sustainable agriculture practices.

Acknowledgment

The authors acknowledge the University of Tunis for organizing the 3rd IEEE International Conference on Intelligence in Business and Industry (IEEE IBI 2026). We thank the researchers who created and shared the agricultural datasets used in this study, particularly Prof. Wisam Dawood Abdullah at the University of Tikrit for the IoT Agriculture datasets.

TABLE III
ACTUATORS, CONTROL TYPES, MODEL E INPUTS, AND SAFETY MEASURES

Actuator	**Control Type**	**Model E Input**	**Safety Measures**
Water Pump	ON/OFF, PWM	pump_volume (L)	Max runtime 30min, dry-run protection
Nutrient Pump	Pulse dosing	nutrient_dose (ml)	Max daily limit, EC/pH check
LED Grow Lights	PWM 0–100%	light_intensity	Max intensity, thermal limit
Heater/Cooler	PID control	target_temp	Min/max temp, interlock
Ventilation Fans	PWM speed	fan_speed	Motor overheat protection
Motorized Vents	Servo position	vent_position	End-stop sensors
Shade Panels	Stepper position	shade_position	Position limits
Solenoid Valves	ON/OFF	zone_valve[i]	Over-watering prevention
UV Lamp	ON/OFF	uv_on (bool)	Human presence lockout
Power Manager	MPC budget	energy_budget	Battery safety limits
Alarm System	Trigger	alert_level	Redundant channels

TABLE IV
SENSOR-TO-MODEL MAPPING AND REAL-TIME CONTROL FLOW

Sensor/Input	**Model**	**Purpose**	**Sampling Rate**
Chlorophyll, Leaf Area, Root	Model A	Plant health classification	Daily/Weekly
N, P, K, pH, Rainfall	Model B	Crop recommendation	Seasonal
NDVI, Weather, Fertilizer	Model C	Yield prediction	Weekly/Monthly
Soil Moisture, Temp, Humidity	Model D	Irrigation control	5–15 minutes
Water Level, Flow Rate	Model D	Water management	Real-time
All Models Outputs	Model E	Meta-optimization	Per decision cycle
